HACKATHON 2026

INSTRUCTIONS FOR SUBMISSION ROUND (Round 2)

1. **Introduction:**
   With increased thrust on infrastructure development, the construction sector will continue to play a key role in India's economic development. An integral part of all infrastructure projects is the legally binding construction contract. While construction contracts ensure clarity in risk allocation, parties often enter into agreements without reviewing the fine print and later face claims and disputes over contract interpretation. One important contract document, often the epicentre of contractual disputes, is the "technical specifications." This document contains the employer's technical requirements and is crucial to determining the project cost. Research points to a lack of time and expertise to review contract documents as a root cause of insufficient analysis and understanding of these documents before signing. Rather, a heavy reliance on the reviewer's experience leads to unpleasant financial surprises during project execution. Here, Natural language processing (NLP) tools can help construction firms quickly and efficiently review technical specifications, identify key material requirements and code provisions, and prepare a simplified method statement so that no aspect is overlooked at the project site. rather than mere experience-based bidding. In this hackathon, teams are tasked with developing an NLP-based tool to generate a simple Method Statement from information in the construction specification. Participants must choose appropriate Natural Language Processing (NLP) techniques \ to develop a tool that automatically populates a method statement template with summarised information from the specification document.

2. **Overall Objective**
   To develop a tool that can automatically populate a method statement template (for concreting works) with summarised information from the corresponding specification document.

3. **Reference Construction Specification Document**
   The reference contract specification document can be downloaded from
   <Insert a Google Drive Link here>
   This document is a technical specification from a public-sector firm. The teams are expected to develop a code and generate a Method Statement for Reinforced Cement Concrete (RCC) work in the format explained in the next section.

4. **Output Requirements**
   The output should contain a Method Statement for RCC work (Word File) with the following items in the Method Statement using the given specification document:
   - Purpose of the Method Statement
   - Scope of the Method Statement
   - Acronyms and Definitions
   - Reference documents
   - Procedure for concreting
   - Equipment used
   - Key people involved
   - Any other information that is relevant

Note:

1. The total pages in the Method Statement should not exceed 6 pages.
2. The information in the Method Statement should be concise, yet comprehensive.
3. The information in the Method Statement should be from the Specification only, and in case of extraction of data from external sources, it should be referred to clearly in the document.
4. The code should be able to extract information from any specification document and should not be restricted to one type of document only.
5. The teams should also submit the original specification document with highlighted sections and information regarding the inputs referred/extracted to prepare the method statement.
6. The teams must also suggest a suitable metric to assess the model's accuracy. However, the final decision on the accuracy values will be made based on the metric the organisers will use during the evaluation.
7. If the team qualifies for Round 3, the judges may give any document, and the qualified teams must be able to extract a similar table from the given document.

5. **The following output files are expected to be submitted for this round by 04/05/2026 23:59 hours. The submission link can be found on the Unstop portal.**

   a. **Output file (.pdf format)**
      - This file should contain the extracted solutions in a MS WORD FILE strictly in a format as described in the 'Output Requirements' (Section 4) above.
      - The file should be submitted in MS WORD format.
      - The file's first page should contain your Unstop Team ID/Team Name & all the team members, highlighting the leader.

   b. **Presentation (.pdf format)**
      - This presentation should contain the extracted solutions for the five questions above in the format explained in the 'Output Requirements' (Section 4) above.
      - The Presentation should be limited to 12 Slides (including the title slide). Any team that exceeds this limit will be automatically disqualified.
      - The presentation should be submitted in .pdf format to prevent anyone from using animations.
      - The title slide of the presentation should contain your Unstop Team ID & all the names of members of the team, highlighting the leader.

   c. **Zipped version of Folder Containing Code (.pynb Format) & Supporting files (.zip format)**
      - The code file format should be. pynb and should be able to run in Google Collab independently with the data file as input in the form of .csv or any other format in the same zipped folder.
      - The code should be free from errors and checked before submission. Any code that won't work directly on Google Collab will be rejected.
      - Teams must provide hashed-out text in the code sections to explain how the commands are utilised for the problems.

   d. **5-minute video (.mp4 format)**
      - The teams can use any graphics or presentation mode, including the Python code / Slides / Results, etc.

- The teams are expected to cover five main points in the video as given below:
  - **Explainability** - How does the developed code function for the specific case?
  - **Output conformance** – How the output confirms the requirements as explained in the section on "Output Requirements."?
  - **Novel Understanding** - What insights can be generated and explained from the results?
  - **Innovation –** How does your model exceed expectations beyond what is mentioned under "Output Requirements?"
  - **Accuracy** – How do you demonstrate your model accuracy in the information extracted? How do you establish that the output is free from hallucination?

NOTE: If there are file upload issues, please contact the organisers immediately

6. **Evaluation criteria (100% split)**
   - Code quality - 10% (Clear documentation, coding guidelines, proper refactoring)
   - Compliance with output requirement (minimum requirements) format – 50%
   - Innovation - 10%
   - Performance /accuracy of the solution – 20%
   - Scalability/potential for large-scale deployment - 10%
   - Minimum for qualification to Round 3 – 70%

7. **Other important notes**
   - The decision of the organisers will be final and binding
   - Participants should make their own arrangements for APIs/access to Language Models if needed. The organisers will not be providing any API/Language Model access.
   - Contact the organisers (contact details available on Unstop) if any clarifications are required.
   - Teams cannot use commercially available software.
